

Pilot

Television-Led Adoption, Live Intelligence, Moments, and Agent Network Strategy

Tessaris / AION Product and Technical Record

29 August 2026

Strategy decision following Fabric version 0.14.0

Abstract

This document records the decided product and distribution strategy for Pilot, the consumer-facing intelligence operating on the AION Device Fabric. Pilot will not initially be marketed as a general personal agent, household operating system, or abstract artificial-intelligence platform. Its entry product is a highly demonstrable proposition: add conversational intelligence to the television a person already owns, without requiring a new television or dedicated AI appliance. Entertainment, games, learning, search, live screen intelligence, and moment sharing provide acquisition and immediate delight. Once installed, the same governed mother brain becomes useful for reminders, messages, calendars, shopping, booking, navigation, device control, safety, and person-to-person agent handoffs. The television is therefore the adoption wedge; Pilot Actions creates habit; Pilot Relay creates network growth; cross-device continuity creates retention.

1 Status of this Record

This is a product decision and implementation direction, not a claim that all described capabilities are already complete. The current Fabric proof has already demonstrated discovery and governed control of an existing LG webOS television, a mother node, a private phone controller, local voice activation, television search and navigation, cloud-gaming composition, an interactive learning centre, household persona boundaries, capability capsules, compact device updates, and an auditable action chain. Pilot Live, Pilot Moments, cross-household Relay, car continuation, and emergency escalation are the next strategic layers and require the additional work identified below.

Decided approach. The name *Pilot* is the consumer identity and spoken activation word. AION Device Fabric remains the underlying technical substrate, governance system, node architecture, memory, and execution boundary.

2 Core Product Thesis

Consumers are unlikely to seek out and install a new “personal autonomous AI agent” merely because it exists. That description is abstract and asks for trust before demonstrating value. By contrast, the proposition

“Add Pilot to the television you already own.”

is concrete, visual, inexpensive to understand, and easy to demonstrate to another person. The user first experiences Pilot as an extraordinary upgrade to a familiar device. The broader personal agent emerges through use rather than through an onboarding lecture.

Decided approach. AI television is the primary acquisition product. It is not a distraction from the general agent: it is the mechanism by which the general agent enters the home, earns trust, pairs with the phone, learns permitted preferences, and becomes available for wider action.

The product should therefore be positioned in the following order:

1. **Install:** give an existing television Pilot capabilities.
2. **Delight:** demonstrate entertainment control, games, learning, live understanding, search, and social sharing.
3. **Habit:** let the user create reminders, lists, messages, calendar actions, research tasks, and shopping requests naturally.
4. **Expansion:** continue the same identity, memory, and objective on the phone, computer, car, and other authorised nodes.
5. **Network:** let useful moments and structured intents move to other people and their Pilots.
6. **Retention:** preserve trusted context, preferences, completed work, device relationships, and verified service connections.

3 The Adoption Funnel

Stage	What the user believes they installed	What Pilot is becoming
Hook	AI for an existing television	A governed mother brain inside the home
Delight	Entertainment, games, learning, search, and live intelligence	Screen context, service knowledge, and useful memory
Habit	Reminders, lists, messaging, comparison, and scheduling	A personal action agent
Expansion	Phone, computer, car, calendar, and connected devices	One continuous intelligence across surfaces
Network	Sharing moments and requests with other people	A permissioned person-to-person agent network
Retention	“Pilot already understands how I work”	A persistent, trusted intelligence layer

The strategic relationship between the principal engines is:

Pilot TV acquires users → Pilot Live creates wonder → Pilot Moments spreads → Pilot Actions creates daily use → Pilot Relay creates network effects → Pilot Everywhere creates permanence.

4 Pilot Live: Intelligence for Anything on Screen

Pilot Live is the immediate room-scale intelligence layer. It should understand the current programme, application, conversation, event, and available metadata sufficiently to answer and act on requests such as:

- “Pilot, fact-check that.”
- “Pilot, who is telling the truth here?”
- “Pilot, explain what just happened without spoilers.”

- “Pilot, translate what she just said.”
- “Pilot, who is that actor?”
- “Pilot, find the original source.”
- “Pilot, explain that referee decision.”
- “Pilot, teach the children the science behind this scene.”
- “Pilot, is that advertised product actually any good?”
- “Pilot, remember this; we should discuss it later.”

The differentiation is not the answer alone. Pilot can move the answer into memory, a message, a task, a shopping comparison, an educational activity, a calendar item, a phone, a car, or a handoff to another person.

4.1 Flagship fact-check proof

The first headline demonstration should be:

**“We made an ordinary television fact-check a live broadcast
when you speak to it.”**

The intended flow is:

1. A factual statement is made in a live or recorded programme.
2. The viewer says, “Pilot, fact-check that.”
3. Pilot identifies the relevant recent statement and extracts its falsifiable claims.
4. The mother brain searches current, attributable evidence, preferring primary sources and clearly separating fact, inference, uncertainty, and disagreement.
5. A compact television overlay displays a plain-language finding, confidence, and the most important comparison without unnecessarily replacing the programme.
6. The user can ask a contextual follow-up such as “show me the evidence” without repeating the activation word during the bounded dialogue window.
7. Full sources and private detail transfer to the paired phone.

Because restricted LG televisions do not expose a supported general-purpose screen-capture interface to third-party applications, the initial proof should fuse bounded evidence rather than claim perfect visual access:

- a short, ephemeral, memory-only audio ring buffer;
- local speech transcription triggered for use only by an explicit request;
- foreground application, media, and programme-guide metadata;
- streaming-service title and playback-position evidence where exposed;
- phone-camera observation when visual evidence is necessary;
- claim extraction, current research, source grading, and contradiction detection; and

- a sanitized TV overlay plus a private evidence view on the phone.

Audio in the rolling buffer must be overwritten continuously and must not be persisted by default. An explicit user action is required before derived transcript content is retained as part of a request or audit receipt.

5 Pilot Moments: Entertainment as the Viral Loop

Pilot Moments turns something seen on television into a social object. The canonical demonstration is:

“Pilot, share the last thirty seconds with Mike.”
 “I found the moment. Send it to Mike?”
 “Yes.”

If Mike already has Pilot, the moment can open on his phone or television and retain its conversational context. If Mike does not have Pilot, he receives a normal secure link or provider-supported share. The landing surface delivers the value first and only then offers *Watch on TV with Pilot*. The content therefore sells the product more effectively than an abstract invitation to an AI platform.

5.1 Service-aware sharing hierarchy

Pilot must not bypass copyright controls, DRM, service terms, or access controls. “Clip that” is a user intent whose permitted execution depends on the active source:

1. **Provider-native clip.** Invoke an official clipping function when the creator and service permit it. Twitch, for example, exposes viewer clip creation and authorised sharing.[2]
2. **Provider-native moment.** Invoke an authorised moment-saving flow such as Netflix Moments when it is exposed to the signed-in user and available on the relevant device or service surface.[1]
3. **Timestamp link.** Share the official title at the precise playback position where the service supports deep linking. YouTube is moving toward Share at Timestamp as its principal viewer-sharing mechanism.[3]
4. **Pilot Moment Card.** When video export is unavailable, create a copyright-safe card containing the title, episode, timestamp, official watch link, user reaction, short contextual description, and an “open at this moment” action where supported.
5. **Media export.** Create a video file only for user-owned, public-domain, explicitly licensed, or provider-authorised content.

Protected streams are intentionally encrypted and access-controlled; Pilot must integrate with their approved interfaces rather than attempting to defeat those protections.[4]

5.2 Moment object

A normalized moment record should contain no more information than necessary:

<code>moment_id</code>	signed opaque identifier
<code>sender_persona</code>	public/contact identity, not account credentials
<code>service</code>	netflix youtube twitch broadcast other
<code>content_reference</code>	provider title identifier or programme identifier

position	timestamp or bounded live-window reference
share_mode	native_clip native_moment timestamp moment_card
reaction	sender-approved text or voice-derived caption
recipient	selected Pilot contact or external share destination
permissions	expiry, replay, forwarding, and audience policy
evidence_hash	hash of the normalized context used to prepare the share

The card must not reveal a household member’s viewing history, service token, profile identity, private transcript, location, or unrelated context.

6 Pilot Actions: The Personal Agent Revealed Through Use

After installation for television intelligence, the user naturally begins to delegate ordinary work:

- “Pilot, add that to my to-do list.”
- “Pilot, remind me tomorrow.”
- “Pilot, message John that I will be twenty minutes late.”
- “Pilot, reply to that email and say Thursday works.”
- “Pilot, put this in my calendar.”
- “Pilot, order more dog food.”
- “Pilot, find the best three options and send them to my phone.”
- “Pilot, arrange someone to repair the boiler.”
- “Pilot, move the delivery to Friday.”
- “Pilot, send this destination to the car.”

Shopping comparison is therefore a capability of Pilot Actions rather than a separate strategic product. The durable execution pattern remains:

**Understand → research → prepare exact action → private approval → execute once
→ verify → receipt.**

Shared television speech must never silently choose a person’s card, account, calendar, recipient, or private identity. Consequential actions transfer to the relevant person’s private phone and connected service adapter.

7 Pilot Relay: Person-to-Person Agent Handoffs

Pilot Relay is the distribution engine. Its central insight is:

The sender creates the recipient’s first useful Pilot task before the recipient has installed Pilot.

For example, one person says:

“Pilot, ask Kevin to collect the dry cleaning on his way home.”

The sender’s Pilot creates a signed proposal, not a remote command. Kevin’s Pilot may respond privately:

“Becca asked you to collect the dry cleaning on your way home. Shall I remind you when you leave work and add it to your route?”

If Kevin accepts, his own Pilot—not Becca’s—chooses an appropriate reminder time, checks closing hours, and offers the stop to the navigation surface. On completion, it asks whether Kevin wants to send an acknowledgement. Becca does not gain access to Kevin’s location, calendar, route, contacts, or messages.

7.1 Structured intent rather than unstructured messaging

Relay should transport a typed, bounded proposal:

```
type:      task
from:      sender contact identity
to:        recipient contact identity
action:    collect
object:    dry cleaning
window:    journey home
location:  recipient-resolved usual dry cleaner
status:    proposed
return:    optional completion acknowledgement
```

Additional handoff types include message, event, invitation, recommendation, shopping item, location, document, payment request, decision, emergency alert, introduction, moment, and shared plan. Typed objects let the recipient’s Pilot reason about time, place, interruption, dependencies, and permitted execution without conflating every request with ordinary chat.

7.2 Installed and uninstalled recipients

If the recipient has Pilot, the proposal is delivered through the recipient’s trusted contact and capability policy. If the recipient does not have Pilot, the system sends a conventional, sender-approved message containing a secure temporary page. The recipient can accept, add the request to an existing phone tool, decline without creating an account, or activate Pilot. Contact discovery and SMS invitation are established low-friction patterns in existing communications products.[5]

Pilot must support households but must not be limited to a rigid household account. The useful graph includes partners, children, parents, friends, colleagues, neighbours, carers, tradespeople, school contacts, and temporary groups. Conventional family-account systems are often deliberately small; for example, Google documents a family manager inviting up to five other people.[6] Pilot instead requires a permissioned contact graph and temporary or persistent *Circles* for household, trip, school, care, work, and friend contexts.

7.3 Non-negotiable trust rule

Decided approach. One person’s Pilot must never command another person’s Pilot. The sender’s Pilot proposes; the recipient’s Pilot evaluates; the recipient controls acceptance, scheduling, disclosure, execution, and acknowledgement.

Recipient policies must support at least:

- always allow ordinary reminders from selected contacts;
- require confirmation before calendar modification;
- never share location or presence by default;

- silence non-urgent proposals during protected periods;
- allow explicitly configured emergency interruption;
- block, mute, expire, or rate-limit a contact;
- forbid purchases or payments requested by another person;
- prevent private proposals from appearing on communal screens; and
- apply transparent, age-appropriate guardian policy for children and teenagers without creating invisible surveillance.

Every handoff requires signed sender identity, intended recipient, expiry, nonce or replay protection, scope, audit receipt, and a human-readable preview.

8 Pilot Companion, Guardian, Everywhere, and Work

8.1 Pilot Companion

Pilot Companion provides contextual conversation rather than a detached chatbot. It may discuss the active programme, remember permitted preferences, explain confusing material, conduct quizzes, continue a conversation on another device, and help a user contact family. It must not claim to be human, manipulate emotional dependence, manufacture urgency, or interrupt without a user-controlled policy. Warmth and continuity are product qualities; honesty and user agency are system requirements.

8.2 Pilot Guardian

The long-term safety proposition includes requests such as “Pilot, help me”, “Pilot, I have fallen”, and “Pilot, call an ambulance”. A safe proof may acknowledge the call, display a large emergency interface, contact configured trusted people, share explicitly authorised location, and open a two-way response surface. Automatic emergency-service escalation cannot be marketed or relied upon until the system has jurisdiction-specific authorised calling, reliable identity and location, connectivity fallback, false-positive handling, health and emergency review, continuous availability monitoring, and a tested failure protocol. Guardian is safety infrastructure, not an ordinary voice shortcut.

8.3 Pilot Everywhere

The intelligence must continue across surfaces rather than being copied into unrelated assistants. A restaurant shortlist created on the television can move privately to the phone; the selected destination can later appear in the car; a voice note from the car can become a work task; a household request can become an authorised navigation stop. The same persona, objective, memory, permissions, and audit chain continue while each surface receives only the capabilities and data appropriate to it.

8.4 Pilot Work

Work mode remains a high-value expansion: live briefings, research walls, meeting preparation, document review, operational dashboards, scenario analysis, action extraction, and governed execution. It is deliberately not the initial consumer acquisition message. The television-led consumer proof establishes the cross-device substrate on which a later room-scale work and Boardroom product can operate.

9 Fabric Architecture Required by the Strategy

Fabric component	Strategic responsibility
Mother brain	Reasoning, planning, service orchestration, private memory, persona resolution, policy, and recovery.
Universal node identity	Stable public identity and stored handshakes that allow one device node to serve multiple independently authorised mothers.
Television gateway/node	Governed control, current-service evidence, Canvas presentation, and verified restricted-device actions.
Private phone companion	Identity selection, private detail collection, contact choice, camera observation, approval, and consequential-action receipt.
Pilot Live context layer	Ephemeral recent-audio context, metadata fusion, claim extraction, current research, and evidence-labelled response.
Moment adapter layer	Provider-native clips, moments, timestamp links, and copyright-safe fallback cards.
Relay envelope	Signed typed proposal with recipient, scope, expiry, replay protection, privacy policy, status, and optional acknowledgement.
Service adapters	Calendar, email, messaging, tasks, maps, shopping, booking, media, and later authorised emergency providers.
Audit and glyph ledgers	Compact, verifiable records of permission, action, state transition, handoff, outcome, and reconstruction without raw secret data.

10 Decided Implementation Sequence

Phase 1: Pilot Live and Pilot Moments

1. Add the ephemeral recent-audio context buffer and explicit activation boundary.
2. Fuse current application, content, programme, playback-position, and phone-observer evidence into a normalized live-context object.
3. Implement “fact-check that”, “explain that”, “translate that”, and contextual follow-up on the television and phone.
4. Implement the service-aware moment hierarchy: native share, timestamp, Moment Card, or explicit refusal.
5. Add private contact selection and a single-recipient share receipt.

Phase 2: Pilot Contacts and Relay

Implement contact identity, signed invitations, installed-recipient delivery, temporary value-first web delivery for uninstalled recipients, typed handoff objects, recipient policies, expiry, replay protection, acknowledgement, and block/mute controls.

Phase 3: Pilot Actions

Connect real user-authorised task, messaging, calendar, email, maps, shopping, and booking services to the existing prepare–approve–execute–verify flow. Moment and Relay objects then become direct inputs to useful action.

Phase 4: Pilot Everywhere

Provide phone background continuity, car-safe voice interaction, authorised navigation handoff, location-triggered reminders, and multi-surface objective resumption without exposing private state to unrelated nodes.

Phase 5: Pilot Guardian and Pilot Work

Develop Guardian only with the necessary reliability, emergency, privacy, and regulatory partners. Expand Work and Boardroom mode using the proven identity, handoff, service, and room-scale presentation layers.

11 Success Measures

The strategy should be measured as a behavioural system, not merely as a list of available commands:

- time from download to first successful television action;
- percentage of activated households pairing a private phone;
- first-day use of a Live command or Moment share;
- successful provider-native or timestamp share rate;
- percentage of recipients receiving value before installation;
- recipient-to-Pilot activation conversion;
- accepted Relay proposals per active contact pair;
- weekly use of at least one Pilot Action outside entertainment;
- cross-surface continuation rate among television, phone, and car;
- false activation, failed execution, reversal, and complaint rates;
- percentage of consequential actions with explicit private approval and verified outcome; and
- user-controlled deletion, mute, block, and privacy-policy effectiveness.

Growth must not be optimized by dark patterns, involuntary contact uploads, silent invitations, public exposure of private viewing, or pressure to accept another person's request. A network of personal agents is valuable only if each person remains sovereign over their own agent.

12 Final Product Position

Pilot should not initially ask the market to understand an autonomous agent, a device fabric, or a household operating system. It should make one promise:

Add Pilot to the television you already own.

The demonstration then proves that Pilot can understand, fact-check, find, remember, and share what the user is watching. Entertainment creates the installation; live intelligence creates the story people repeat; Moment sharing creates the invitation; Actions creates daily utility; Relay turns individual utility into a network; and continuity across phone, home, and car makes the intelligence indispensable.

Screen → understanding → action → another person.

This is the decided approach: the television is the visible beginning, not the product boundary. Pilot enters through entertainment and becomes a governed, persistent personal intelligence through demonstrated usefulness.
